9 **28 ABSTRACT**

10
11 29

12
13
14 30 Relatively little is known about the influence of sex and the circadian rhythm on
15
16 31 gastrointestinal transit. However, these factors could have an important impact on
17
18 32 aspects such as digestion, oral absorption of drugs or the clinical manifestation of
19
20 33 gastrointestinal diseases, among others. Remarkably, preclinical models have scarcely
21
22 34 taken these factors into consideration. In this study, we assessed the gastrointestinal
23
24 35 transit of young adult Wistar Han rats of both sexes, under normal and inverted light
25
26 36 cycle. To do this, serial radiographs were taken for 24h (T0-T24) after intragastric barium
27
28 37 administration and subsequently analyzed to construct transit curves for each
29
30 38 gastrointestinal region. Under a normal light cycle, transit curves were similar, except
31
32 39 for a slower transit in females compared with males from T8 to T24. Under the inverted
33
34 40 cycle, there was a significant acceleration in stomach emptying (similar in both sexes),
35
36 41 emptying of the small intestine (even faster in females) and filling of the caecum and
37
38 42 colon (which was also even faster in females). This study confirms, using X-ray non-
39
40 43 invasive methods for the first time, that both, sex and circadian rhythm (probably
41
42 44 through its effect on behavior) influence gastrointestinal transit in laboratory animals.

9 **47 INTRODUCTION**

10
11 **48** Gastrointestinal transit may be influenced by many factors that cause relevant inter- and
12
13 **49** intra-subject variability, both in human and animal models. Amid these factors, the role
14
15 **50** of sex and the circadian rhythm on gastrointestinal transit has been scarcely studied
16
17 **51** although they could be important factors in processes such as digestion, oral absorption
18
19 **52** of drugs or gastrointestinal pathologies, among others.
20
21
22
23
24
25

26 **54** In relation to the impact of sex, early human studies showed a shorter gastrointestinal
27
28 **55** transit time in healthy men compared to women¹⁻⁴. Recent data further support the
29
30 **56** concept that men have faster gastric emptying and intestinal transit than women⁵. Sex
31
32 **57** hormones, on the one hand, and the phases of the menstrual cycle, on the other, are
33
34 **58** important variables to consider.⁶ With respect to the circadian rhythm, most life forms
35
36 **59** engage a 24-hour cycle of feeding and fasting.⁷ However, relatively little attention has
37
38 **60** been paid to the investigation of the relationship between the circadian rhythm and the
39
40 **61** functions of the alimentary tract.^{8,9} For example, one early study compared colonic
41
42 **62** transit in healthy patients using 24-hour ambulatory colonic manometry, and showed
43
44 **63** significant less pressure activity in the colon during daylight hours in women when
45
46 **64** compared to men.¹⁰ Similarly, in a recent investigation in mice, both sex and time of the
47
48 **65** day when the experiments were carried out significantly influenced intestinal transit.¹¹

1
2
3
4
5
6
7
8
9 66 In general, preclinical studies have used invasive techniques to evaluate the effects of
10
11 67 sex and/or circadian rhythm on gastrointestinal motor function.¹¹ An attractive and non-
12
13 68 invasive alternative is the use of radiographic techniques, which allow the study of
14
15 69 gastrointestinal transit and changes in size and density of the gastrointestinal regions
16
17 70 using radiopaque contrast.¹² Until now, we and others have used these techniques to
18
19 71 evaluate the impact on gastrointestinal transit of different drugs as well as to analyze
20
21 72 gastrointestinal transit in aged or stressed animals, or in those exposed to different
22
23 73 dietary modifications (see supplementary Table I for references). However, these
24
25 74 studies were carried out with rodents (mainly male or both sexes, without comparison)
26
27 75 under normal light cycle (lights on during the day: animals are studied in their low-
28
29 76 activity circadian phase) (supplementary Table I). To our knowledge, radiographic
30
31 77 studies which compare gastrointestinal transit in male and female laboratory animals
32
33 78 under both normal and inverted light cycles are lacking.
34
35
36
37
38
39
40
41 79
42
43 80 Therefore, the aim of this study was to evaluate the effect of sex and the circadian cycle
44
45 81 on gastrointestinal transit, using radiographic techniques.

9 **85 METHODS AND MATERIALS**

10
11 **86 *Animals***

12
13
14 **87** The experiments were designed and performed in accordance with the EU Directive for
15
16 **88** the Protection of Animals Used for Scientific Purposes (2010/63/EU) and Spanish
17
18 **89** regulations (Law 32/2007, RD 53/2013 and order ECC/566/2015) and were approved by
19
20
21 **90** the Ethical Committee at Universidad Rey Juan Carlos (URJC) and Comunidad Autónoma
22
23 **91** de Madrid (PROEX 063/18, PROEX 023/19). The health and welfare of the animals used
24
25
26 **92** for the study was supervised by the personnel of the URJC Veterinary Unit where the
27
28
29 **93** study was performed. All experiments were designed to minimize the number of animals
30
31 **94** used and their suffering.

32
33 **95**

34
35
36 **96** Male (N=24; weight= 342-520 g) and female (N=24; weight= 191-270 g) sexually-mature,
37
38 **97** young adult (3-4 months old) Wistar HAN healthy rats were obtained from the
39
40
41 **98** Veterinary Unit of URJC and housed (2-4/cage), after simple randomization, in standard
42
43
44 **99** transparent cages (60 x 40 x 20 cm) in a temperature (20°C) and humidity-controlled
45
46 **100** room (60%), with a 12 h light/12 h dark cycle (lights off between 20:00 and 08.00 hours
47
48 **101** for animals with normal light cycle conditions or between 8.00 and 20:00 hours for
49
50 **102** animals with inverted light-dark cycle). Animals were divided in 4 groups (N=12/group):
51
52
53 **103** Males, Normal Cycle (M-N) (this was considered the control or reference group); Males,
54
55
56
57
58
59
60

1
2
3
4
5
6
7
8
9 104 Inverted Cycle (M-I); Females, Normal Cycle (F-N); Females, Inverted Cycle (F-I). Animals
10
11 105 had free access to standard laboratory rat chow (LASQ diet® Rod 14-A www.altromin.de)
12
13
14 106 and tap water until sacrifice.

15
16 107 *Gastrointestinal transit*

17
18 108 Gastrointestinal motor function was evaluated once in the URJC animal facility,
19
20
21 109 radiographically, as described.¹² Prior to the X-ray assay, the experimental animals were
22
23
24 110 not fasted, due to the long duration of the X-ray study (24 h), but all of them were
25
26 111 weighed, and the estrous cycle phase of females was analyzed by vaginal cytology.^{13,14}
27
28 112 In addition, their health conditions were observed before and during the experimental
29
30
31 113 procedures, i.e. the appearance and color of the hair coat, legs, eyes and nose and also
32
33 114 their behavior and movement. For the radiographic evaluation, barium sulfate
34
35 115 suspension (Barigraph® AD, Juste SAQF, Madrid, Spain; 2 g mL⁻¹ in tap water,
36
37 116 temperature=22°C, 2.5 mL) was administered by gavage at 9 am and serial radiographs
38
39
40 117 were obtained at 0, 1, 2, 4, 6, 8 and 24 h (T0-T24) after contrast administration. Plain
41
42
43 118 facial radiographs of the gastrointestinal tract were obtained using a CS2100
44
45 119 (Carestream Dental, Madrid, Spain) digital X-ray apparatus (60 kV, 7 mA), and X-rays
46
47
48 120 were recorded on Carestream Dental T-MAT G/RA film (15×30 cm) housed in a cassette
49
50
51 121 provided with regular intensifying screen. Exposure time for X-ray shots was set to 0.02
52
53 122 seconds and focus distance was manually fixed to 50±1 cm. Immobilization of the rats
54
55
56
57
58
59
60

1
2
3
4
5
6
7
8
9 123 in prone position was achieved by placing them inside hand-made transparent plastic
10
11 124 tubes (recording chamber), which were adjusted to the size of the rat so they could not
12
13
14 125 move, scape or turn around (Fig. S1). Moreover, training was not necessary, because, as
15
16 126 shown before, this procedure does not cause stress-induced alterations in
17
18 127 gastrointestinal transit.¹² Radiographs were then developed using a Kodak X-OMAT 2000
19
20
21 128 automated processor (Kodak AG, Stuttgart, Germany). For each animal, radiographs
22
23
24 129 were taken in the same order at each time point, so that time intervals between shots
25
26 130 were of the same duration for all animals.

27
28 131 The analysis of the radiographs was performed by a trained investigator who was
29
30
31 132 blinded to the experimental groups. Transit curves were constructed for each
32
33 133 gastrointestinal region (stomach, small intestine, caecum and colorectum) using a semi-
34
35
36 134 quantitative score, assigning a range of values to each region considering the following
37
38 135 parameters (Fig. S2): percentage of the region filled with contrast (0–4); contrast
39
40
41 136 intensity (0–4); contrast homogeneity (0–2); and sharpness of the profile of the gut
42
43 137 region (0–2). Each of these parameters was scored and summed (0–12 points). In
44
45
46 138 addition, the size and density of the barium contrast were analyzed for stomach,
47
48 139 caecum, and fecal pellets, with the aid of an image analysis system (Image J 1.38 for
49
50
51 140 Windows, National Institute of Health, USA, free software: <http://rsb.info.nih.gov/ij/>).

1
2
3
4
5
6
7
8
9 141 The number of fecal pellets within the colorectum was also determined for each rat at
10
11 142 each time point.

12
13
14 143 Moreover, at T0, right after the administration of barium, the animals were placed in
15
16 144 new cages with fresh bedding and the feces present in the cage at each time point of
17
18 145 the radiographic session (T1-T24) were collected. The following parameters were
19
20 146 measured: the % of labeled feces and their radiopacity; the weight of the feces at
21
22 147 collection and after drying them in an oven (70 °C, 24-48 h); their moisture (dry vs. wet
23
24 148 fecal material, as difference).

25
26
27
28
29 149

30
31 150 *Statistical analysis*

32
33 151 Sample size for each experiment was estimated using G*power assuming $\alpha = 0.05$ and
34
35 152 power = 0.8 and 2-tailed tests. Mean and SD for the variables of the control group in the
36
37 153 gastrointestinal transit experiments were based on those obtained in our previous
38
39 154 study.¹²

40
41
42
43 155 Data were analyzed using Graph PadPrism, v. 7.0.[®]. Data are presented as the mean
44
45 156 values \pm SEM. All the data obtained during the experiments were included in the
46
47 157 statistical analysis, and no animal was excluded from the analysis. Each animal was
48
49 158 considered as an experimental unit when analyzing the differences related to transit,
50
51 159 whilst the cages were considered as the experimental unit when analyzing the data
52
53
54
55
56
57
58
59
60

1
2
3
4
5
6
7
8
9 160 related to feces. All data passed the D'Agostino and Pearson's normality test, thus
10
11 161 differences between groups were analyzed using unpaired Student's t-test, with Welch's
12
13 162 correction when appropriate, or one- or two-way ANOVA followed by Tukey post-hoc
14
15 163 multiple comparison tests. The differences between female groups regarding the
16
17 164 distribution of the estrous cycle phases were analyzed with the Chi-square test. Values
18
19 165 of $P < 0.05$ were regarded as being significantly different.
20
21
22
23
24 166

25 26 167 **RESULTS**

27 28 168 *Animal characteristics at T0*

29
30 169 Body weight was significantly lower in females when compared to males. Additionally,
31
32 170 the average weight of M-I was significantly higher than that of M-N (Fig. 1A).
33
34
35

36 171

37
38 172 As seen in Fig. 1B, just before the X-ray scan, all phases of the estrous cycle (Fig. 1C)
39
40 173 were represented in F-N whereas only three of them were represented in F-I. However,
41
42 174 these differences were not statistically significant ($p = 0.3$).
43
44
45

46 175

47 48 176 *Radiographic analysis of gastrointestinal motor function*

49 50 177 *Semiquantitative analysis*

51
52
53
54
55
56
57
58
59
60

1
2
3
4
5
6
7
8
9 178 Gastric emptying in animals under normal cycle (M-N, F-N) was progressive from barium
10
11 179 administration (T0) until the end of the study (T24) without statistically significant
12
13 180 differences between sexes (Fig. 2A, 2F). Likewise, gastric emptying of the animals under
14
15 181 inverted-cycle (M-I, F-I) was similar between males and females, but significantly faster
16
17 182 compared to their sex-matched group under normal cycle. (Fig. 2A, 2F).
18
19
20

21 183
22
23 184 In the small intestine, as in the stomach, the inverted cycle groups showed a significantly
24
25 185 faster emptying of the small intestine than the normal-cycle ones (Fig. 2B, 2F).
26
27 186 Additionally, no significant sex-dependent differences were found in animals with the
28
29 187 same cycle, except for a faster intestinal emptying in F-I compared to M-I at T2, and a
30
31 188 higher barium content in F-N compared to M-N at T24 (Fig. 2B).
32
33
34
35

36 189
37
38 190 In the normal-cycle groups, barium reached the caecum at T2 after administration and
39
40 191 completely filled this organ by T4 (Fig. 2C, 2F). Caecum emptying only started after T8,
41
42 192 and at T24 it was almost empty in M-N but not in F-N (Fig. 2C, 2F). In the inverted-cycle
43
44 193 groups, caecum filling was slightly but significantly faster at T2 and its emptying was also
45
46 194 slightly faster in the inverted-cycle animals, although at T24 M-I was significantly slower
47
48 195 than M-N and F-I was significantly faster than F-N and M-I, and similar to M-N (Fig. 2C,
49
50 196 2F).
51
52
53
54
55
56
57
58
59
60

1
2
3
4
5
6
7
8
9 197

10
11 198 Finally, in the normal-cycle groups barium reached the colorectum at T4 after
12
13 199 administration and completely filled this organ by T8, with no significant differences
14
15
16 200 between sexes. Nevertheless, at T24, whilst in M-N the colorectum was almost
17
18 201 completely empty again, in F-N it showed significantly more barium (Fig. 2D, 2F). Again,
19
20 202 colorectum filling was, in general, faster in the inverted-cycle groups, particularly in F-I,
21
22 203 which reached the colorectum already at T2 (Fig. 2D, 2F). At T24 all groups showed more
23
24 204 barium than M-N in the colorectum (Fig. 2D).
25
26
27
28
29
30

31 205

32 206 *Fecal pellet number in the colorectum*

33 207 The number of fecal pellets counted in the colorectum followed the same trend as the
34
35 208 semiquantitative score in this organ, with no differences found in the amount of feces
36
37 209 observed between F-N and M-N, except at T24 (Fig. 2D, 2E). Likewise, the occurrence of
38
39 210 fecal pellets was accelerated in the animals under inverted cycle, particularly in females,
40
41 211 although males presented a much larger amount of feces than females, with the
42
43 212 maximum number occurring at T6 in both sexes, whereas it was at T8 in the normal cycle
44
45
46 213 groups (Fig. 2E).
47
48
49

50 214

51
52 215 *Morphometric and densitometric analysis*
53
54
55
56
57
58
59
60

1
2
3
4
5
6
7
8
9 216 The morphometric (size) and densitometric (contrast density) analysis of stomach,
10
11 217 caecum and fecal pellets showed similar changes throughout the experiment, as those
12
13
14 218 found in the semiquantitative study. Thus, here we will focus on the maximum values
15
16 219 obtained for size and contrast density of these items.
17
18
19 220

20
21 221 The maximum size of the stomach at T0, was around 480-550 mm², except for F-I, which
22
23 222 was significantly smaller, around 376 mm² (Fig. 3A). The maximum gastric density, also
24
25 223 obtained at T0, was close to 100% for all groups (Fig. 3B).
26
27
28 224

29
30
31 225 In contrast, the maximum size of the caecum was slightly, but significantly, smaller in
32
33 226 females than in males, regardless of the type of light cycle (Fig 3C). When analyzing the
34
35 227 density, all groups reached similar maximum values at T2-T4, without statistically
36
37 228 significant differences at these time points (Fig. 3D).
38
39
40

41 229
42
43 230 Finally, the fecal pellet area and density values were averaged between T4 and T8 (when
44
45 231 these values reached their maximum). The maximum size was similar for all groups,
46
47 232 around 70-85 mm² except for F-I which was significantly smaller, around 53 mm² (Fig.
48
49 233 3E). With respect to barium density, the fecal pellets of the M-I group had a lower
50
51 234 density than the M-N group, whilst no differences were observed due to the cycle in
52
53
54
55
56
57
58
59
60

1
2
3
4
5
6
7
8
9 235 females. Furthermore, the density in the F-I group was higher when compared to M-I
10
11 236 (Fig. 3F).

12
13
14 237

15
16 238 *Characteristics of the feces collected during the X-ray session*

17
18 239 Figure 4A shows representative images of barium-stained and non-stained fecal pellets
19
20
21 240 at T24. Rats expelled 0-4 fecal pellets per hour, without significant differences among
22
23 241 groups (Fig. S3A). The percentage of expelled stained fecal pellets increased in all groups
24
25
26 242 in a time-dependent manner, with the F-I group being significantly faster than the other
27
28 243 groups, followed by M-I, M-N and F-N, in that order (Fig. 4B). The radiopacity pattern
29
30 244 was similar to that of the % of stained fecal pellets, but interestingly M-I practically
31
32
33 245 overlapped with M-N throughout the whole study, whilst significant differences in the
34
35
36 246 radiopacity along time were found between F-N and F-I (Fig. 4C).

37
38 247

39
40 248 To evaluate the moisture of the feces, the difference between wet and dry weight (wet
41
42
43 249 weight – dry weight; Fig. S3B and C show these parameters individualized) was
44
45
46 250 calculated. All the groups had similar values throughout the experiment except M-N
47
48 251 group at T1, when the difference was significantly greater compared to the rest of the
49
50 252 groups. The other groups had a value of about half of that found in M-N at T1 (Fig. 4C).

9 254 **DISCUSSION**

10
11 255 Although many different techniques have been used to analyze gastrointestinal transit
12
13 256 in laboratory animals (for example, see Table S1 in ¹⁵), non-invasive techniques are
14
15 257 preferable for both ethical reasons and translatability. In the present study we have
16
17 258 demonstrated, for the first time using non-invasive radiographic techniques, the effects
18
19 259 of the circadian rhythm and its related behavior and that of sex on gastrointestinal
20
21 260 transit. Importantly, our results agree with those of other researchers using other
22
23 261 invasive or indirect techniques,^{11,16} with the advantages of including a relatively low
24
25 262 number of animals and obtaining more detailed information from the different
26
27 263 gastrointestinal organs along time.
28
29
30
31
32
33

34 264 *X-ray study of gastrointestinal transit in male rats under normal light cycle*
35
36
37

38 265 In this 24-hour study, we used the M-N group as a reference, in the same way as in most
39
40 266 rodent X-ray studies, including those carried out by our research group in rats
41
42 267 (Supplementary Table I), since the transit patterns are well established in these animals.
43
44 268 As expected, in this study the transit pattern in M-N group was similar to that previously
45
46 269 found by other authors and also by our group.^{12,17-19}
47
48
49
50

51 270 The present study benefits from the performance of a comprehensive analysis of the
52
53 271 fecal pellets collected during the radiographic session. The percentage of stained fecal
54
55
56
57
58
59
60

1
2
3
4
5
6
7
8
9 272 pellets showed a progressive increase from T4 to T24. Similar to the number of stained
10
11 273 fecal pellets within the colorectum, radiopacity increased up to T8 and decreased
12
13 274 afterwards. Since radiopacity is measured using the average of all fecal pellets, the
14
15 275 decrease at T24 is a reflection of the production of new pellets (without staining) during
16
17 276 the night, when animals are more active and also eat more.²⁰⁻²²

18
19
20
21
22 277 The increased moisture (associated with highest wet fecal matter expulsion, Fig. S3B) of
23
24 278 the fecal pellets collected at T1 (Fig. 4D), probably reflects some level of psychological
25
26 279 stress, since increased fecal moisture and fecal production are generally considered as
27
28 280 indirect markers of stress in male rats.²³

29
30
31
32
33 281 *X-ray study of gastrointestinal transit in female rats under normal light cycle*

34
35
36 282 To our knowledge, no previous study has specifically evaluated the influence of sex on
37
38 283 gastrointestinal transit using radiographic methods in rodents. In the few radiographic
39
40 284 studies in which females were used, results from animals of both sexes were either
41
42 285 combined²⁴⁻²⁸ or evaluated separately without a specific comparison²⁹ and
43
44 286 methodological differences (including animal species) preclude proper comparison with
45
46 287 our results. In the present study, the F-N transit curves were similar to those of M-N
47
48 288 from the moment of barium administration (T0) until T8 for all regions, but from this
49
50 289 point till T24 gastrointestinal transit was delayed in F-N. Although early human studies
51
52
53
54
55
56
57
58
59
60

1
2
3
4
5
6
7
8
9 290 showed shorter gastrointestinal transit times in healthy men compared to healthy
10
11 291 women,¹⁻⁵ our results suggest that, under normal light conditions, gastrointestinal
12
13
14 292 transit is equivalent in rats of both sexes for the first 8 h, when the animals are relatively
15
16 293 inactive, eat less and, consequently, their gastrointestinal motility is less stimulated
17
18 294 (which could be somehow similar to fasting in humans). Afterwards, during the activity
19
20
21 295 phase, transit of the large intestine appears to be delayed in females compared to males,
22
23 296 with a certain degree of retention of barium-stained content in both the caecum and
24
25
26 297 colorectum. The reduction in the maximum size of the caecum found in females, is
27
28 298 probably related to its sexual dimorphism in body weight.^{30,31} However, these
29
30
31 299 morphometric differences would have favored a faster transit in the large intestine.
32
33 300 Thus, they do not seem to contribute to the transit differences between the two sexes
34
35
36 301 under normal cycle.

37
38
39 302 In F-N, the curve for the percentage of stained fecal pellets showed a similar pattern to
40
41 303 those of M-N, except for the fact that at T8 no stained fecal pellet was recovered from
42
43 304 the cage. Interestingly, the absence of stained fecal pellets in the cage at T8 was
44
45
46 305 followed by a slight increase in stomach size and small intestine staining at T24 in this
47
48
49 306 group of animals, maybe due to coprophagia, which is a common behavior in rats.^{32,33}
50

56
57
58
59
60

1
2
3
4
5
6
7
8
9 307 A difference between sexes, unlikely related with their body weight, was the fact that at
10
11 308 T1 females produced less fecal matter with significantly lower moisture. Interestingly, in
12
13 309 a previous study also performed in male and female mice under normal light cycle, we
14
15 310 found similar results.³⁴ In that study, mice were isolated in cages without bedding for 4
16
17 311 hours after intragastric administration of barium and the fecal pellets produced were
18
19 312 radiographically analyzed. Despite the evident methodological differences, in both
20
21 313 species, males produced more feces and with more moisture at the beginning of the
22
23 314 study than at later moments, reflecting a certain level of initial stress, perhaps
24
25 315 associated with the manipulation (barium administration) and the new conditions (new
26
27 316 cage). This phenomenon may reflect some important dimorphism in rodent biology that
28
29 317 deserves further investigation regarding its mechanisms and function and could be
30
31 318 attributed to differences in the gastrocolic response to mechanical stimulation of the
32
33 319 stomach by barium administration and/or psychological stress associated with the initial
34
35 320 handling and exposure to the new environment, aforementioned.^{23,35}

36
37
38
39
40
41
42
43
44 321 *Influence of the circadian rhythm on the gastrointestinal transit of male and female rats*

45
46
47 322 Although the impact of the circadian rhythm on gastrointestinal transit has been
48
49 323 evaluated in different species, including humans,³⁶⁻³⁸ to the best of our knowledge, it
50
51 324 has never been addressed in laboratory animals using radiographic methods.
52
53
54
55
56
57
58
59
60

1
2
3
4
5
6
7
8
9 325 Compared with M-N, M-I showed much faster transit in the upper gastrointestinal tract
10
11 326 (stomach and small intestine) and faster filling and emptying of the caecum and the
12
13
14 327 colorectum during the first 8 h of the study. However, emptying of caecum and
15
16 328 colorectum was delayed at T24. These results were expected, since in the M-I group the
17
18 329 experiments performed from T0-T8 occur during their activity phase, when animals
19
20
21 330 move, eat, and defecate more. ^{20-22,39}
22
23
24
25 331 Interestingly, the moisture of the fecal pellets did not increase at T1 in M-I as seen for
26
27 332 M-N, suggesting that during their activity phase the males might be less sensitive to the
28
29 333 stress produced by the new experimental conditions (transport to the X-ray room,
30
31 334 barium gavage, brief restraint...) than during their inactivity phase.
32
33
34
35 335 Finally, in F-I, gastric emptying was similar to that of M-I but emptying of the small
36
37 336 intestine and caecum was much faster in F-I than in any other group, including F-N,
38
39 337 leading to much faster colorectum filling which was also reflected in a higher percentage
40
41 338 of expelled stained pellets at earlier times. Furthermore, female groups were not
42
43 339 significantly different in terms of their body weight or their distribution among estrous
44
45 340 phases, suggesting that these factors had little contribution to our transit results. In the
46
47 341 morphometric analysis, F-I animals showed smaller stomach (at T0) and fecal pellets (at
48
49 342 T4-T8), but their maximum caecum size (at T4-T6) was not significantly different from
50
51
52
53
54
55
56
57
58
59
60

1
2
3
4
5
6
7
8
9 343 that of F-N group. Thus, although we did not measure the small and large intestine
10
11 344 lengths at sacrifice, which would have helped to ascertain this issue, it is unlikely that
12
13 345 the morphometric differences found in the X-rays explain such a fast gastrointestinal
14
15 346 transit in F-I group. Furthermore, a higher level of stress at the beginning of the study
16
17 347 does not seem to underlie the faster transit either, since at T1 the moisture parameters
18
19 348 of fecal pellets were as in M-I and F-N. Nevertheless, our results agree with a recent
20
21 349 invasive study in mice, in which Soni et al¹¹ compared the transit of males and females
22
23 350 at different phases of the day and with different fasting times. They found that females
24
25 351 analysed in the morning had a slower gastrointestinal transit than those analysed in the
26
27 352 afternoon and concluded that females are more sensitive than males to the phase of the
28
29 353 circadian rhythm. Moreover, an indirect study, based on the analysis of the microbiota,
30
31 354 also found differences between the sexes associated with the circadian rhythm.¹⁶
32
33
34
35
36
37
38
39 355 Although other activities, such as locomotor activity, may affect gastrointestinal transit,
40
41 356 the impact of food ingestion is a relevant driving force leading to its acceleration. In this
42
43 357 sense, food ingestion increases during the phase of activity, which corresponds to the
44
45 358 lights off period²⁰. Although fasting is usually imposed in gastrointestinal transit studies
46
47 359 and its duration has an impact on the results,¹¹ in the present study we did not fast the
48
49 360 animals before the experiments for ethical reasons (fasting duration would have been
50
51 361 much longer than 24 h). Therefore, manipulation, which was the same for all animals,
52
53
54
55
56
57
58
59
60

1
2
3
4
5
6
7
8
9 362 was only limited to the unavoidable handling of the animals needed to take the X-rays.

10
11 363 Thus, in this study, the animal activities that normally take place during the different
12
13
14 364 moments of the day were only minimally altered.

15
16
17 365 Finally, it could seem that our results were mainly due to the difference in body weight
18
19 366 displayed by male and female rats (which ranged from 72 to 329 g). In agreement, M-N
20
21
22 367 tended to produce more wet and dry fecal matter than F-N, particularly at T6-T24 (Fig.
23
24
25 368 S3B, C). However, the amount of fecal matter collected from the cage of the animals
26
27 369 under the inverted cycle, was practically the same up to T8, regardless of their sex (Fig.
28
29
30 370 S3B, C). Thus, the differences in body weight alone do not suffice to explain our results
31
32 371 on fecal matter production and gastrointestinal transit.

33 34 35 372 **CONCLUSIONS**

36
37
38
39 373 In the present study, the influence on gastrointestinal transit of sex and the circadian
40
41 374 rhythm and its related behavior was evaluated in the rat using radiographic methods for
42
43
44 375 the first time. When the study was performed under normal light cycle, i.e., during the
45
46 376 inactivity phase of the animals, males and females had similar transit times despite their
47
48 377 different body weight and slightly different defecation. Under an inverse light/dark
49
50
51 378 cycle, animals of both sexes showed an accelerated gastrointestinal transit compared to
52
53
54 379 animals under a normal light cycle, but females displayed an even more accelerated

1
2
3
4
5
6
7
8
9 380 transit when compared to males, although fecal matter production was similar. Thus,
10
11 381 both sex and the circadian rhythm (or its associated feeding and locomotor activities)
12
13
14 382 have a paramount influence on gastrointestinal transit.
15
16
17 383 Our results highlight the need for more detailed studies to precisely define the influence
18
19 384 of sex on the gastrointestinal and other physiological functions, and how these functions
20
21
22 385 change throughout the day.

Table I. Studies using non-invasive radiographic methods to evaluate gastrointestinal motility in small experimental animals (mainly rodents).

Year	Drug or condition studied	Species	Sex of animals	Light cycle phase	Reference
1979	No drug administration. Diabetic animals.	Chinese hamsters	Both, without comparison	N.S.	Diani et al., 1979
1983	Different drugs (dopamine antagonists, apomorphine, atropine, eserine, prazosin, propranolol).	Guinea pig	Both, without comparison	N.S.	Costall et al., 1983
1993	No drug administration. Groups with different ages at the point of X-ray study.	Rat	Female	N.S.	Perry et al., 1993
1994	No drug administration. 1,000 eggs of <i>Taenia taeniaformis</i> dosed orally.	Rat	Female	N.S.	Perry et al., 1994
1995	No drug administration. Dietary fiber (wheat bran) at 0, 20 or 40% (% weight).	Rat	N.S.	N.S.	Munakata et al., 1995
2005	Ethosuximide (150 mg/kg) oral administration for 15 days. One single neostigmine (4 ml kg ⁻¹ 0.25%, i.m.) or metoclopramide (10 mg kg ⁻¹ , i.p.) administration.	Rat	Male	N.S.	Sirakov et al., 2005
2008	One single cisplatin (3 or 6 mg kg ⁻¹ , i.p.) administration.	Rat	Male	Normal	Cabazos et al., 2008
2009	WIN 55,212-2 (0.5 or 5 mg kg ⁻¹ , i.p) administration, once a day for 14 consecutive days.	Rat	Male	Normal	Abalo et al., 2009
2010	One single WIN 55,212-2 (0.5, 1, 2 and 5 mg kg ⁻¹ , i.p.) administration. One single CB1 antagonist AM251 (1 mg kg ⁻¹ , i.p.) and/or the CB2 antagonist SR144528 (1 mg kg ⁻¹ , i.p.) administration.	Rat	Male	Normal	Abalo et al., 2010
2010	Cisplatin (at 1, 2, or 3 mg kg ⁻¹ , i.p.) administration once a week for four weeks	Rat	Male	Normal	Cabazos et al., 2010

2011	WIN 55,212-2 (0.5 or 5 mg kg ⁻¹ , i.p.) administration alone or after CB1 antagonist/ inverse agonist AM251 (1 mg kg ⁻¹ , i.p.) administration, once a week for four weeks.	Rat	Male	Normal	Abalo et al., 2011
2013	One single loperamide (5 or 10 mg kg ⁻¹ , i.p.) administration.	Mice	Female	Inverted	Myagmarjalbuu et al., 2013
2013	WIN 55,212-2 (0.5 or 1 mg kg ⁻¹ , i.p.) and cisplatin (2 mg kg ⁻¹ , i.p.) administrations, once a week for four weeks.	Rat	Male	Normal	Abalo et al., 2013
2014	Loperamide (5 mg kg ⁻¹ , s.c.), metoclopramide (10 mg kg ⁻¹ , i.p.) or milk of magnesia (0.2 mL, gavage) administration.	Mice	Both, without comparison	Normal	Reed et al., 2014
2014	Granisetron (1 mg kg ⁻¹ , i.p.) and, 30 minutes after, cisplatin (2 mg kg ⁻¹ , i.p.), once per week for 4 weeks.	Rat	Male	Normal	Vera et al., 2014
2014	One single 6-OHDA stereotaxic administration in the medial forebrain bundle.	Rat	Male	Normal	Vegezzi et al., 2014
2015	MSG (4 g L ⁻¹) in the drinking water for 6 weeks.	Rat	Male	Normal	López-Miranda et al., 2015
2015	One single AM841 (0.1 or 1 mg kg ⁻¹ , i.p.) or WIN 55,212-2 (5 mg kg ⁻¹ , i.p.) administration. One single CB1 (AM251, 1 mg kg ⁻¹ , i.p.) or CB2 (AM630, 1 mg kg ⁻¹ , i.p.) antagonist administration prior to the agonists.	Rat	Male	Normal	Abalo et al., 2015
2016	One single morphine (5 or 10 mg/kg, i.p.) administration.	Rat /mice	Male	Normal	Girón et al., 2016
2016	Prucalopride or loperamide (1, 2, or 4 mg kg ⁻¹ , s.c.) continuous (osmotic mini-pump) administration, for seven days, in aged animals (18 months-old).	Rat	Male	Normal	Dalziel et al., 2016
2016	5-FU (23 mg kg ⁻¹ , i.p.) administration three times a week for two weeks.	Mice	Male	Normal	McQuade et al., 2016
2017	No drug administration. Genetic model of IBD (Winnie mice).	Mice	Both, without comparison	Normal	Robinson et al., 2017

2017	One single vincristine (0.1 or 0.5 mg kg ⁻¹ , i.p.) administration, alone or with CB1 (AM251) or CB2 (AM630) administered 1-3 times (1 mg kg ⁻¹ , i.p.; 20 min before, 12 h after, 24 after vincristine).	Rat	Male	Normal	Vera et al., 2017
2017	5-FU (150 mg kg ⁻¹ , i.p.) once a day for two consecutive days alone or with WIN 55,212-2 (0.5 mg kg ⁻¹ , i.p.) administration once a day for four days.	Rat	Male	Normal	Abalo et al., 2017
2017	Basal conditions. WKY (stress-prone) rats	Rat	Male	Normal	Dalziel et al., 2017
2017	Prucalopride or loperamide (1, 2, or 4 mg kg ⁻¹ , s.c.) continuous (osmotic mini-pump) administration, for seven days, in aged animals (18 months-old) fed a control or test diet (enriched in milk proteins, whey or casein, hydroized or not).	Rat	Male	Normal	Dalziel et al., 2017
2018	Oxaliplatin (3 mg kg ⁻¹ , i.p.) with or without BGP-15 (15 mg kg ⁻¹ , i.p.) administration three times a week for two weeks.	Mice	Male	Normal	McQuade et al., 2018
2018	Vincristine (0.1 mg kg ⁻¹ , i.p.) administration once daily in 2 cycles of 5 days each.	Rat	Male	Normal	López Gomez et al., 2018
2018	Normal rats at different ages (2-3, 12, 18, 24 months) Streptozotocin (60 mg kg ⁻¹ , i.p.) administration and X-ray evaluation 4 weeks after.	Rat	Male	Normal	Abalo et al., 2018
2019	Coffee silverskin melanoidins in drinking water for 4 weeks.	Rat	Male	Normal	Tores de la Cruz et al., 2019
2019	Granisetron (1 mg kg ⁻¹ , i.p.) followed by cisplatin (6 mg kg ⁻¹ , i.p.) administration 30 minutes after.	Rat	Male	Normal	Martín-Ruíz et al., 2019
2019	5-FU (23 mg kg ⁻¹ , i.p.) administration with or without BGP-15 (15 mg kg ⁻¹ , i.p.) three times a week.	Mice	Male	Normal	McQuade et al., 2019
2019	Spent coffee grounds (1 g kg ⁻¹ , gavage) administration by oral gavage every day for 4 weeks.	Rat	Male	Normal	Iriondo-DeHond et al., 2019

2019	Loperamide (0.1, 1, or 10 mg kg ⁻¹ , i.p.) administration.	Rat	Male	Normal	Vera et al., 2019
2019	Four different diets (standard, AIN-93G and AIN-93G enriched in coconut or evening primrose oil) with a different amount and composition of fatty acids for 4 weeks.	Rat	Male	Normal	Mosinska et al., 2019
2019	LPS (0.1, 1 or 5 mg kg ⁻¹ , i.p.) administration.	Rat	Male	Normal	Abalo et al., 2019
2019	Viral antigen Poly I:C i.p. administration on gestational day 15. X-rays were taken at young adult age of the male offspring.	Rat	Male	Normal	Gálvez et al., 2019
2021	Genetic model of IBD (Winnie mice) treated with APX3330 (25 mg kg ⁻¹ , i.p.) administration, twice daily for 2 weeks	Mice	Both, without comparison	Normal	Sahakian et al., 2021
2021	Three different diets (AIN-93G and AIN-93G enriched in coconut or evening primrose oil) with a different amount and composition of fatty acids for 6 weeks.	Rat	Both, with comparison	Normal	Jacenic et al., 2021
2021	MSG (4 g L ⁻¹) in drinking water for 6 weeks (0-5). Cisplatin (2 mg kg ⁻¹ , i.p.) administration on the first day of weeks 1-5.	Rat	Male	Normal	López-Tofiño et al., 2021
2021	No drug administration. Acute and subchronic stress through forced swim or restrain at 4°C.	Rat	Male	Normal	Bagués et al., 2021

Abbreviations: 5-FU, 5-fluorouracil; 6-OHDA, 6-hydroxydopamine; i.m., intramuscular; ip., intraperitoneal; LPS, lipopolysaccharide; MSG, monosodium glutamate; N.S., not specified; s.c., subcutaneous.
